

Chapter 2B

So

$$\bar{\epsilon} = -\frac{\partial}{\partial(1/kT)} \left[\ln \sum_n e^{-\epsilon_n/kT} \right] = \frac{h\nu}{2} + \frac{\partial}{\partial(1/kT)} [\ln x]$$

$$\bar{\epsilon} = \frac{h\nu}{2} + \frac{(\partial/\partial(1/kT)) [1 - e^{-h\nu/kT}]}{1 - e^{-h\nu/kT}}$$

$$\bar{\epsilon} = \frac{h\nu}{2} + \frac{-\partial/\partial(1/kT) [e^{-h\nu/kT}]}{1 - e^{-h\nu/kT}}$$

$$\bar{\epsilon} = \frac{h\nu}{2} + \frac{h\nu e^{-h\nu/kT}}{1 - e^{-h\nu/kT}}$$

Multiply the second term in the above by $e^{h\nu/kT}/e^{h\nu/kT}$:

$$\bar{\epsilon} = \frac{h\nu}{2} + \frac{h\nu}{e^{h\nu/kT} - 1} \quad (2-37)$$

As $T \rightarrow 0$, $h\nu/kT \rightarrow \infty$. So the 1st term vanishes and $\bar{\epsilon} = h\nu/2$

So this term is the zero point energy.

When T is large, what happens. Expand e^x where $x = h\nu/kT$.

$$\text{Now } e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots$$

Then from (2-37)

$$\bar{\epsilon} = \frac{h\nu}{2} + h\nu \left[1 + \frac{h\nu}{kT} + \underbrace{\left(\frac{h\nu}{kT} \right)^2 \left(\frac{1}{2!} \right) + \dots}_{\text{drop because } T^n \text{ is large when } n > 1} \right]^{-1}$$

$$\bar{\epsilon} = \frac{h\nu}{2} + h\nu \left[\frac{h\nu}{kT} \right]^{-1}$$

$$\bar{\epsilon} = \frac{h\nu}{kT} \rightarrow kT \quad \text{for very large } T.$$

From electromagnetic theory it may be shown that

$$\bar{\epsilon} = \frac{\lambda^4}{8\pi} u_\lambda \quad (2-41)$$

where $u_\lambda d\lambda =$ energy of radiation in the spectral interval $\lambda \rightarrow \lambda + d\lambda$

Now assume that T is sufficiently large that

$$\frac{h\nu}{2} \ll \frac{h\nu}{e^{h\nu/kT} - 1}$$

Then from (2-37) we may write

$$\bar{\epsilon} = \frac{h\nu}{e^{h\nu/kT} - 1} \quad (2-42)$$

Now combine (2-41) and (2-42) to obtain:

$$\frac{\lambda^4}{8\pi} u_\lambda = \frac{h\nu}{e^{h\nu/kT} - 1} \quad (2-43)$$

And so,

$$u_\lambda = \frac{8\pi h\nu}{\lambda^4} \left(\frac{1}{e^{h\nu/kT} - 1} \right) \quad (2-44)$$

It may be shown (Appendix C) that

$$u_{\lambda} = \frac{4}{c} F_{\lambda}, \quad (2-45)$$

so:

$$F_{\lambda} = \frac{2\pi h^2 \nu c}{\lambda^4} \left[\frac{1}{e^{h\nu/kT} - 1} \right] \quad (2-46)$$

Substituting $\nu = c/\lambda$

$$F_{\lambda} = \frac{2\pi hc^2}{\lambda^5} \left[\frac{1}{e^{hc/\lambda kT} - 1} \right] \quad (2-47)$$

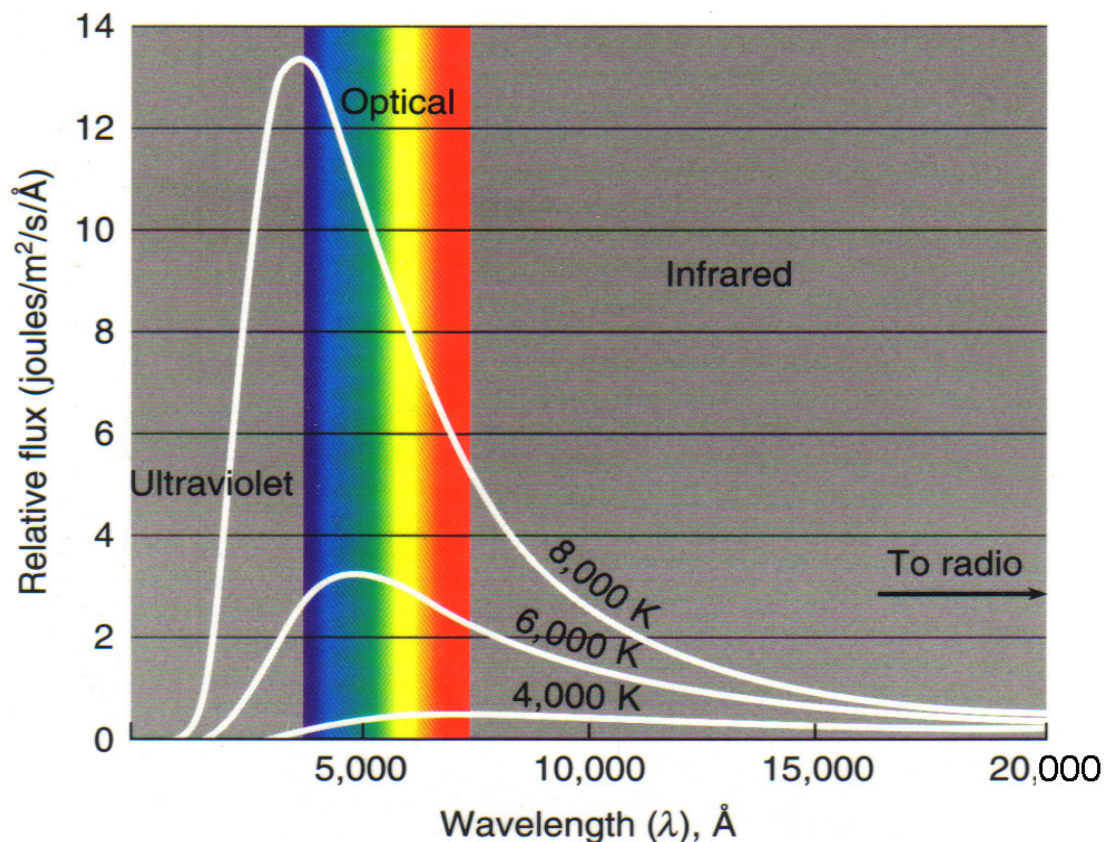

Equation (2-47) is Planck's radiation law. Let B_{λ} be the black-body intensity. Then for an isotropic and homogeneous radiation field, $F_{\lambda} = \pi B_{\lambda}$. Therefore:

$$B_{\lambda} = \frac{2hc^2}{\lambda^5} \left[\frac{1}{e^{hc/\lambda kT} - 1} \right] \quad (2-48)$$

When B_{λ} is plotted versus wavelength for different temperatures, one gets the different curves that are shown in the diagram below. The curves are called "Black-body Curves" or "Planckians."

$$F_{\lambda}(T) = \pi B_{\lambda}(T) = \frac{\pi (1.191 \times 10^{-5}) \lambda^{-5}}{(e^{1.439/\lambda T} - 1)} \quad (2-49)$$

In this equation, λ must be in centimeters and the units for F_{λ} are ergs/cm²/s/cm. **RJP-32, & 33.**

To find λ_{\max} , the wavelength at which F_{λ} is a maximum, we differentiate Planck's law and set the result equal to zero. Solving for λ we get Wien's Displacement Law.

$$\lambda_{\max} = \frac{0.2898}{T} \quad (\lambda \text{ in cm}) \quad (2-50)$$

For λ_{\max} in \AA :

$$\lambda_{\max} = \frac{2.898 \times 10^7}{T} \quad (2-51)$$

If we integrate F_{λ} over all wavelengths we get the bolometric flux

$$F_{\text{bol}} = \int_0^{\infty} F_{\lambda}(T) d\lambda = \sigma T^4 \quad (2-52)$$

Here $\sigma = 5.67 \times 10^{-5} \text{ erg/cm}^2/\text{sec/K}^4$ is the Stefan-Boltzmann constant. We recognize that $F_{\text{bol}} = \sigma T^4$ is the Stefan-Boltzmann Law, the total energy emitted per second from every square cm of a body over the entire EM spectrum. Geometrically, this is the area under any of the curves shown in the diagram above. Also, recall that $L_* = 4\pi R_*^2 \sigma T^4$.

Now consider the case where λ is large. Then $\exp(hc/\lambda kT)$ and $e^x \cong 1 + x + \dots$, where $x = hc/\lambda kT$, so

$$B_{\lambda} \cong (2hc^2/\lambda^5) [1/(1+x-1)] \cong (2hc^2/\lambda^5) [1/(hc/\lambda kT)] \cong 2ckT/\lambda^4,$$

which is the Rayleigh-Jeans approximation. Now consider λ to be small and T not very large, then $hc/\lambda kT \gg 1$. So

$$B_{\lambda} \cong (2hc^2/\lambda^5) [1/\exp(hc/\lambda kT)] \cong (2hc^2/\lambda^5) e^{-hc/\lambda kT},$$

which is the Wien approximation. See Fig. 2, in Chapter 2A.
